

ACCEPTANCE CRITERIA IN FIRE SAFETY ENGINEERING: A REVIEW AND CASE STUDY

Daniel Rosberg

Karl Fridolf

Andre Purchase

Introduction

- Methods to verify safe egress
 - *Qualitative methods*
 - **Scenario-based methods**
 - *Risk-based methods*
- Scenario-based methods
 - *ASET/RSET-analysis*
 - *Fractional effective dose (FED) concept*
- Traditional ASET/RSET analysis
 - *Simple (yet complex)*
 - *Fire model to find ASET*
 - evaluated against **absolute values**
 - *Evacuation software to find RSET*
- Fractional effective dose (FED) concept
 - *More common when evacuation through smoke*
 - *More complex method*
 - *Fire model (CFD) to calculate concentrations*
 - *Evacuation model to calculate dose*

Acceptance criteria for absolute values

- Defined in some building regulations
 - *Sweden*
 - *New Zealand*
- European initiative
 - *Still variation between countries*
- No uniform set of criteria in a global perspective

Criteria	Swedish building regulations ⁽¹⁾ BBRAD 3	New Zealand Building Code ⁽¹⁾ C/VM2
Smoke layer above floor level	Smoke layer > 1.6 + (ceiling height)*0.1 [m]	-
Visibility	Visibility > 10 m (spaces > 100 m ²)	Visibility ⁽²⁾ > 10 m (spaces > 100 m ²)
Visibility	Visibility > 5 m (spaces < 100 m ² or spaces where queuing start early in the evacuation)	Visibility ⁽²⁾ > 5 m (spaces < 100 m ²)
Thermal radiation	Radiation < 2.5 kW/m ² or a short-term radiation of < 10 kW/m ² combined with a maximum energy dose of < 60 kJ/m ² in excess of the energy from a radiation level of 1 kW/m ²	Requirements for radiation exposure along egress routes.
Temperature	Temperature < 80 °C	FED _{thermal} criteria specified
Carbon monoxide toxicity	[CO] < 2000 ppm	FED _{CO} criteria specified
Carbon Dioxide toxicity	[CO ₂] < 5%	-
Oxygen availability	[O ₂] > 15%	-
FED	-	FED _{CO} < 0.3 FED _{thermal} < 0.3 ⁽²⁾

Acceptance criteria for absolute values

- Simple to work with
 - Low sensitivity to changes in the combustibles
 - Generally well accepted
- Required inputs
 - *Fire size,*
 - *Growth rate,*
 - *CO yield,*
 - *CO₂ yield,*
 - *Soot yield*
 - *Heat of combustion*
 - ...

FED tenability acceptance criteria

- Some design situations require alternative measures to assess the consequences of a certain fire scenario
 - *When exposed to smoke during longer durations*
 - *Road tunnels*
 - *Rail tunnels*
 - *Sprinklered buildings*
- It is common that the responsibility lies with the designer to assess:
 - *the methodology to use*
 - *Which asphyxiant (and/or irritant) gases to consider*
 - *acceptable accumulated dose to verify life safety against*

FED tenability acceptance criteria

- Common values

- $FED < 1.0$

- 50 % of the population being susceptible

- $FED < 0.3$

- 11 % of the population being susceptible

- Input yield data

- *highly dependent on fire conditions*

- *Difficult to find reliable information (seldom reported)*

Purpose and goals

“Investigate the consequences of applying different methods and acceptance criteria to verify fire life safety.”

Goals:

1. *How the fire safety outcome is affected by the method used (i.e. absolute values or FED).*
2. *How the fire safety outcome is affected by the acceptance criteria (e.g. different acceptance criteria for the same variable)*
3. *Address the challenges an engineer faces when working with alternative methods and acceptance criteria compared to traditional or regulated approaches.*

Case study: Geometry

- Simple geometry
 - IMO test 10
 - Cabin arrangement on a passenger ship
 - 12 cabins
- People asleep
 - No movement
 - 23 occupants

Case study: Geometry

- FDS 6.7.0
- Grid size 5 to 10 cm
- Room height 2.8 m
- Openings at exits
 - Door width \times 0.6 m
- Fire source in Cabin #9
- Data recorded at 2 m height

Yield	Units	BBRAD 3	NIST sofa [‡]
Peak fire size (no sprinklers)	MW	5	-*
Growth rate (t-squared)	kW/m ²	0.047	-*
Heat of combustion	MJ/kg	20	-*
Fraction of Hydrogen in soot	-	0.1 [†]	0.1 [†]
Yields (per gram of fuel consumed)			
Soot	[g/g]	0.1	-*
Carbon Dioxide (CO ₂)	[g/g]	2.5	1.59
Carbon Monoxide (CO)	[g/g]	0.1	0.0144
Hydrogen Cyanide (HCN)	[g/g]	-	0.0035
Hydrogen Chloride (HCl)	[g/g]	-	0.018
Nitrogen Dioxide (NO ₂)	[g/g]	-	0.07
Acrolein (C ₃ H ₄ O)	[g/g]	-	0.008
Formaldehyde (CH ₂ O)	[g/g]	-	0.02

Methodology: Two cases

- BBRAD 3 case
 - *Well defined input data and acceptance criteria*
 - *CO, CO₂ and soot*
 - **Simple chemistry**
 - Single mixing-controlled reaction
 - Fuel molecule contains only C, O, H, and N.
 - $C_{4.56}H_{6.56}O_{2.34}N_{0.4}$
- NIST Sofa case
 - *HCN, HCl, NO₂, C₃H₄O and CH₂O also considered*
 - **Complex chemistry**
 - Additional species were lumped in the model
 - The volume fractions calculated from the stoichiometric coefficients of the primitive species

Results: BBRAD 3 case

- ⊕ BBRAD Criteria 1 - Layer > 1.6 + 0.1*ceiling height [m]
- ⊗ BBRAD Criteria 2a - Visibility > 10 m in rooms > 100 m²
- BBRAD Criteria 2b - Visibility > 5 m in rooms < 100 m²
- ◻ BBRAD Criteria 3 - Radiation < 2.5 kW/m²
- ◊ BBRAD Criteria 4 - Temperature < 80 °C
- ◇ BBRAD Criteria 5a - CO < 2000 ppm
- ✕ BBRAD Criteria 5b - CO₂ < 5%
- ◻ BBRAD Criteria 5c - O₂ > 15%
- △ FED < 0.3
- △ FED < 1.0
- △ FIC < 1.0

13

Results: NIST Sofa case

- ⊕ BBRAD Criteria 1 - Layer > 1.6 + 0.1*ceiling height [m]
- ⊗ BBRAD Criteria 2a - Visibility > 10 m in rooms > 100 m²
- BBRAD Criteria 2b - Visibility > 5 m in rooms < 100 m²
- BBRAD Criteria 3 - Radiation < 2.5 kW/m²
- ◇ BBRAD Criteria 4 - Temperature < 80 °C
- ◇ BBRAD Criteria 5a - CO < 2000 ppm
- ⊗ BBRAD Criteria 5b - CO₂ < 5%
- BBRAD Criteria 5c - O₂ > 15%
- △ FED < 0.3
- △ FED < 1.0
- △ FIC < 1.0

14

- + BBRAD Criteria 1 - Layer > 1.6 + 0.1*ceiling height [m]
- × BBRAD Criteria 2a - Visibility > 10 m in rooms > 100 m²
- BBRAD Criteria 2b - Visibility > 5 m in rooms < 100 m²
- BBRAD Criteria 3 - Radiation < 2.5 kW/m²
- ◇ BBRAD Criteria 4 - Temperature < 80 °C
- ◇ BBRAD Criteria 5a - CO < 2000 ppm
- × BBRAD Criteria 5b - CO₂ < 5%
- BBRAD Criteria 5c - O₂ > 15%
- △ FED < 0.3
- △ FED < 1.0
- △ FIC < 1.0

Discussion: How the fire safety outcome is affected by the method used?

- Using FED as a criteria will allow for longer ASET compared to using absolute tenability criteria
 - *Impaired visibility is the tenability criteria first exceeded*
 - *Takes 4-8 times longer for FED to exceed 0.3 (without additional species)*
- As more species were added
 - *FIC<1 matches the visibility criteria*
 - *Less difference between FED<0.3 and visibility*
 - *The “simple model” became a good indicator of ASET*

Discussion: How the fire safety outcome is affected by the acceptance criteria ?

- The tenability criteria for visibility (both 5 and 10 m) and layer height is exceeded roughly at the same time
 - *Two-zone model?*
 - *Different layer height criteria would most likely have little influence on the results*
- Difficult to estimate in the BBRAD case since $FIC < 1$ and $FED < 1$ were not exceeded
- With additional species
 - *$FIC < 1$ was first exceeded*
 - *$FED < 0.3$ approx. one minute later*
 - *$FED < 1$ approx. one minute after $FED < 0.3$*

Discussion: The challenges an engineer face

- Applying absolute tenability criteria to a case is pretty straight-forward
 - *Mandated input data and acceptance criteria reduce the risk of not getting approval*
- Using FED concepts is more difficult
 - *No uniform agreement on acceptance criteria*
 - *No uniform agreement on which species to add*
 - *Difficult to find reliable data (a big part of this study)*
 - *Complex chemistry might introduce a greater risk of user-error*
- The tools (FDS) can handle the complexity
- Evacuation models need to account for reduced walking speed in smoke

Thank you!
